SUMMARY

Global-local mixtures are derived from the Cauchy-Schlömilch and Liouville integral transformation identities. We characterize well-known normal-scale mixture distributions including the Laplace or lasso, logit and quantile as well as new global-local mixtures. We also apply our methodology to convolutions that commonly arise in Bayesian inference. Finally, we conclude with a conjecture concerning bridge and uniform correlation mixtures.

15

Some key words: Bayes regularization; Cauchy; Convolution; Global-local mixture; Lasso; Logistic; Quantile; Stable law.

20

1. INTRODUCTION

Many statistical problems involve regularization penalties derived from global-local mixture distributions (Polson & Scott, 2011; Hans, 2011; Bhadra et al., 2016a). A global-local mixture density, denoted by $p(x_1, \dots, x_p)$, takes the form

25

$$p(x_1, \dots, x_p) = \int_0^\infty \prod_{i=1}^p p(x_i | \tau) p(\tau) d\tau,$$

where $p(x_i | \tau) = \int_0^\infty p(x_i | \lambda_i, \tau) p(\lambda_i | \tau) d\lambda_i$ is a local mixture and $p(x_1, \dots, x_p)$ is a global mixture over $\tau \sim p(\tau)$. There is great interest in analytically calculating $p(x_i | \tau)$, and the associated regularization penalty $\phi(x_i, \tau) = -\log p(x_i | \tau)$. Convolution mixtures of the form $p(x_i | \tau) = \int p(x_i - \lambda_i) p(\lambda_i) d\lambda_i$ are also of interest. We show how the Cauchy-Schlömilch and Liouville transformations can be used to derive closed-form global-local mixtures. We start by stating two key integral identities: the Cauchy-Schlömilch transformation

30

$$\int_0^\infty f \{ (ax - bx^{-1})^2 \} dx = \frac{1}{2a} \int_0^\infty f(y^2) dy, \quad (1)$$

and the Liouville transformation

$$\int_0^\infty f\left(ax + \frac{b}{x}\right) x^{-1/2} dx = a^{-1/2} \int_0^\infty f\left\{2(ab)^{1/2} + y\right\} y^{-1/2} dy, \quad a, b > 0. \quad (2)$$

See Boros et al. (2006), Baker (2008) and Jones (2014) for further discussion. Identity (1) follows from the simple transformation $t = b/(ax)$ as

$$I = \int_0^\infty f\{(ax - b/x)^2\} dx = \int_0^\infty f\{(at - b/t)^2\} \frac{b}{at^2} dt.$$

35 Adding the two terms in the last equality yields $2I = \int_0^\infty f\{(at - b/t)^2\} \{1 + b/(at^2)\} dt$ and transforming $y = b/t - at$ gives $dy = -a\{1 + b/(at^2)\} dt$, which yields $I = (2a)^{-1} \int_0^\infty f(y^2) dy$, as required. A useful generalization of the Cauchy-Schlömilch transformation is

$$\int_0^\infty f[\{x - s(x)\}^2] dx = \int_0^\infty f(y^2) dy, \quad (3)$$

40 where $s(x) = s^{-1}(x)$ is a self-inverse function such as $s(x) = b/x$ or $s(x) = -a^{-1} \log\{1 - \exp(ax)\}$. The proof for the Liouville transformation identity follows in a similar manner, and is omitted for the sake of brevity. These identities can be used to construct new global-local mixture distributions. Let $f(x) = 2g\{t(x)\}$ and let $t(x)$ be of the form $x - s(x)$, where $s : \mathbb{R}^+ \rightarrow \mathbb{R}^+$ is a self-inverse, onto and monotone decreasing function. Together with the Cauchy-Schlömilch transformation, we have a rather surprising way to represent the resulting $g\{t(x)\}$ as a global-
45 local scale mixture.

Jones (2014) shows that only a few choices of $t(x)$ leads to fully tractable formulae for its inverse $t^{-1} = \Pi$ and the integral $\Pi(y) = \int_{-\infty}^y \pi(\omega) d\omega$. Two special choices are the t -distribution with 2 degrees of freedom and the logistic.

$$\begin{aligned} \Pi_T(y) &= (1/2)\{y + (4b + y^2)^{1/2}\}, \Pi_T^{-1}(x) = t_T(x) = x - b/x, \quad b > 0, \\ 50 \quad \Pi_L(y) &= a^{-1} \log(1 + e^{ay}), \Pi_L^{-1}(x) = t_L(x) = a^{-1} \log(e^{ax} - 1), \quad a > 0. \end{aligned}$$

Now, the integral identity in (1) shows that if $f(x)$, $x \geq 0$ is a density function, so is $g(x) = 2af(|ax - b/x|)$, $x > 0$. The functions f and g are called mother and daughter density functions, respectively.

55 Apart from simplifying proofs involving global-local mixtures, the Cauchy-Schlömilch and Liouville transformations can generate new distributions via scale transformations. These transformations can take the form $f(x) = 2g\{t(x)\}$ for certain $f(x)$ under suitable conditions. For example, given a density $f(x)$ we can create a new global-local scale family, $f(ax - b/x)$, by effectively reallocating its probability mass. A particularly useful tool for generating univariate and multivariate random variables is Khintchine's theorem. Khintchine's theorem states that any
60 random variable X with a unimodal, univariate distribution and a mode at zero can be written as a product $X = ZU$, where $U \sim \mathcal{U}(0, 1)$ and Z has the density function $f_Z(z) = -zf'_X(z)$, $z \in \mathbb{R}$. Bryson & Johnson (1982), and subsequently Jones (2002), discuss how Khintchine's theorem allows one to construct both univariate and multivariate densities, even with special dependence structure. Jones (2014) develops an extended Khintchine's theorem that further allows one to
65 generate random variables with unimodal densities of the form $2g\{t(x)\}$.

2. GLOBAL-LOCAL SCALE MIXTURES

2.1. Lasso as a normal scale mixture

The lasso penalty arises as a Laplace global-local mixture (Andrews & Mallows, 1974). A simple transformation proof follows using Cauchy-Schlömilch with $f(x) = e^{-x}$. Starting with the normal integral identity, $\int_0^\infty f(y^2)dy = \int_0^\infty e^{-y^2}dy = \pi^{1/2}/2$, we obtain

70

$$\int_0^\infty e^{-(ax)^2 - (b/x)^2} dx = \int_0^\infty \exp \left\{ -ab \left(\frac{a}{b}x^2 + \frac{b}{a}x^{-2} \right) \right\} dx = \frac{\pi^{1/2}}{2a} e^{-2ab} \quad a, b \in \mathbb{R}.$$

Substituting $t = (a/b)^{1/2}x$ and $c = ab$ yields the Laplace or Lasso penalty as

$$\int_0^\infty e^{-c(t-t^{-1})^2} dt = \frac{1}{2}(\pi/c)^{1/2} \Rightarrow \int_0^\infty e^{-c(t^2+t^{-2})} dt = \frac{1}{2}(\pi/c)^{1/2} e^{-2c}.$$

The Laplace density can be viewed as a transformed normal, via $y = t - t^{-1}$.

PROPOSITION 1. *The usual identity for the lasso also follows from Lévy (1940) as*

$$\int_0^\infty \frac{a}{(2\pi)^{1/2}t^{3/2}} e^{-a^2/(2t)} e^{-\lambda t} dt = e^{-a(2\lambda)^{1/2}}. \quad (4)$$

For $a = 1$, and $\theta = (2\lambda)^{1/2}$, this can be written as

75

$$E[\exp\{-\theta^2/(2G)\}] = \exp(-\theta), \quad G \sim \mathcal{G}(1/2, 1/2) \quad (5)$$

Proof. First substitute $t^{-1} = x^2$, which makes the left hand side in (4) equal to

$$\int_0^\infty \frac{a}{(2\pi)^{1/2}t^{3/2}} e^{-a^2/(2t)} e^{-\lambda t} dt = \left(\frac{2}{\pi}\right)^{1/2} a e^{-a(2\lambda)^{1/2}} \int_0^\infty e^{-(2^{-1/2}ax - \lambda x^{-1})^2} dx = e^{-a(2\lambda)^{1/2}}.$$

The last step follows from Cauchy-Schlömilch formula. The second relationship (5) follows by fixing $a = 1$, $\theta = (2\lambda)^{1/2}$ and substituting $t = x^{-1}$

$$\int_0^\infty \frac{a}{(2\pi)^{1/2}t^{3/2}} e^{-a^2/(2t)} e^{-\lambda t} dt = \frac{1}{(2\pi)^{1/2}} \int_0^\infty e^{-\theta^2/(2x)} x^{-1/2} e^{-x/2} dx.$$

The left hand side can be identified as $E\left\{e^{-\theta^2/(2G)}\right\}$ for $G \sim \mathcal{G}(1/2, 1/2)$. \square

2.2. Logit and quantile as global-local mixtures

80

Logistic modeling can be viewed within the global-local mixture framework via the Pólya-Gamma distribution (Polson et al., 2013). This leads to efficient Markov chain Monte Carlo algorithms for inference.

PROPOSITION 2. *The two key marginal distributions for the hyperbolic generalized inverse Gaussian (Barndorff-Nielsen et al., 1982) and Pólya-Gamma mixtures are*

85

$$\frac{\alpha^2 - \kappa^2}{2\alpha} e^{-\alpha|x-\mu| + \kappa(x-\mu)} = \int_0^\infty \phi(x | \mu + \kappa\lambda, \lambda) p_{\text{GIG}} \left\{ \lambda | 1, 0, (\alpha^2 - \kappa^2)^{1/2} \right\} d\lambda, \quad \alpha \geq \kappa \geq 0, \quad (6)$$

$$\frac{1}{B(\alpha, \kappa)} \frac{e^{\alpha(x-\mu)}}{(1 + e^{x-\mu})^{\alpha+\kappa}} = \int_0^\infty \phi(x | \mu + \kappa\lambda, \lambda) p_{\text{Polya}}(\lambda | \alpha, \kappa) d\lambda, \quad (7)$$

where $\phi(\mu + \kappa\lambda, \lambda)$ denotes the normal density function with mean $(\mu + \kappa\lambda)$ and variance λ . The functions p_{GIG} and p_{Polya} are the corresponding local mixture densities for the generalized

90 *inverse Gaussian and the Pólya-Gamma, respectively. The logit and quantile identities can be derived using Cauchy-Schlömilch identity.*

Proof. Let $f(x) = e^{-x^2/2}$, $a = \alpha$ and $b = |x - \phi|$ in (1). Then,

$$(2/\pi)^{1/2} \int_0^\infty \exp \left\{ -\frac{1}{2} \left(\alpha y - \frac{|x - \mu|}{y} \right)^2 \right\} dy = \frac{1}{\alpha} (2\pi)^{-1/2} \int_0^\infty e^{-\frac{1}{2}y^2} dy = \frac{1}{\alpha}.$$

Let $\nu = y^2$. Rearranging the constant terms yields

$$\frac{1}{\alpha} e^{-\alpha|x-\mu|} = \frac{1}{(2\pi\nu)^{1/2}} \int_0^\infty \exp \left[-\left\{ \frac{(x-\mu)^2}{2\nu} + \frac{\alpha^2}{2}\nu \right\} \right] d\nu.$$

Multiplying by $2^{-1}(\alpha^2 - \kappa^2)e^{\kappa(x-\mu)}$ and completing the square yields

$$\frac{\alpha^2 - \kappa^2}{2\alpha} \exp \{ -\alpha|x - \mu| + \kappa(x - \mu) \} = \int_0^\infty \phi(x | \mu + \kappa\nu, \nu) \frac{\alpha^2 - \kappa^2}{2} \exp \left(-\frac{\alpha^2 - \kappa^2}{2}\nu \right) d\nu.$$

95 The mixing distribution is exponential with rate parameter $(\alpha^2 - \kappa^2)/2$, a special case of the generalized inverse Gaussian distribution introduced by Etienne Halphen circa 1941 (Seshadri, 2004). The density with parameters $(\lambda, \delta, \gamma)$ has the form

$$p_{\text{GIG}}(x | \lambda, \delta, \gamma) = \frac{(\gamma/\delta)^\lambda}{2K_\lambda(\delta\gamma)} x^{\lambda-1} \exp \left\{ -\frac{1}{2}(\delta^2 x^{-1} + \gamma^2 x) \right\}, \quad x, \lambda, \delta > 0, p \in \mathbb{R},$$

where K_λ is the modified Bessel function of the second kind. The Liouville formula can be used to show that the above is a valid probability density function. When δ or γ is zero, the
100 normalizing constant takes the limiting values given by $K_\lambda(u) \asymp \Gamma(|\lambda|)2^{|\lambda|-1}u^{|\lambda|}$ for $\lambda > 0$. If $\delta = 0$, the generalized inverse Gaussian is identical to a gamma distribution:

$$p_{\text{GIG}}(x | \lambda, \delta = 0, \gamma) = \frac{\alpha^\lambda}{\Gamma(\lambda)} x^{\lambda-1} \exp(-\alpha x), \quad x > 0, \alpha = \gamma^2/2.$$

We now present a simple proof for the Pólya-Gamma mixture in (7). First, write κ for $a - b/2$:

$$\frac{(e^\psi)^a}{(1 + e^\psi)^b} = 2^{-b} e^{\kappa\omega} \int_0^\infty e^{-\omega\psi^2/2} p(\omega) d\omega, \quad (8)$$

where $\omega \sim \text{PG}(b, 0)$, a Pólya-Gamma random variable with density

$$p(\omega | b, 0) = \frac{2^{b-1}}{\Gamma(b)} \sum_{n=0}^\infty (-1)^n \frac{\Gamma(n+b)}{\Gamma(n+1)} \frac{2n+b}{(2\pi)^{1/2} \omega^{3/2}} \exp \left\{ -\frac{(2n+b)^2}{8\omega} \right\}.$$

The logit function corresponds to $a = 0, b = 1$ in (8). Cauchy-Schlömilch identity yields

$$\frac{1}{1 + e^\psi} = \frac{1}{2} e^{-\psi/2} \int_0^\infty e^{-(\psi^2\omega)/2} p(\omega) d\omega, \quad p(\omega) = \sum_{n=0}^\infty (-1)^n \frac{2n+1}{(2\pi\omega^3)^{1/2}} e^{-(2n+1)^2/(8\omega)}. \quad (9)$$

To show (9), write the right-hand side interchanging the integral and summation:

$$105 \quad I = \frac{1}{2} e^{-\psi/2} \sum_{n=0}^\infty (-1)^n \frac{2n+1}{(2\pi)^{1/2}} \int_0^\infty \exp \left[-\left\{ \frac{\psi^2}{2}\omega + \frac{(2n+1)^2}{8\omega} \right\} \right] \frac{1}{\omega^{3/2}} d\omega.$$

Using the change of variable $\omega = t^{-2}$ gives

$$I = \sum_{n=0}^{\infty} (-1)^n e^{-(n+1)\psi} \frac{2n+1}{(2\pi)^{1/2}} \left(\int_0^{\infty} \exp \left[-\frac{1}{2} \left\{ \frac{(2n+1)t}{2} - \frac{\psi}{t} \right\}^2 \right] dt \right).$$

Applying the Cauchy-Schlömilch identity to the inner integral yields

$$\int_0^{\infty} \exp \left[-\frac{1}{2} \left\{ \frac{(2n+1)t}{2} - \frac{\psi}{t} \right\}^2 \right] dt = \int_0^{\infty} \frac{e^{-y^2/2}}{2n+1} dy = \frac{(2\pi)^{1/2}}{2n+1},$$

which implies $I = \sum_{n=0}^{\infty} (-1)^n \exp\{-(n+1)\psi\} = \{1 + \exp(\psi)\}^{-1}$. \square

Remark 1. When $\alpha = \kappa$, we have the limiting result $(\alpha^2 - \kappa^2)^{-1} p_{\text{GIG}}\{1, 0, (\alpha^2 - \kappa^2)^{1/2}\} = 1$, or equivalently in terms of densities, with a marginal improper uniform prior, $p(\lambda) = 1$, 110

$$\int_0^{\infty} \phi(b \mid -a\lambda, c\lambda) d\lambda = a^{-1} \exp\{-2 \max(ab/c, 0)\}. \quad (10)$$

This pseudo-likelihood represents support vector machines as a global-local mixture. The identity for quantile regression, which is a limiting case of the above identities by applying Fatou-Lebesgue theorem, is the following:

$$c^{-1} \exp\{2c^{-1} \rho_q(b)\} = \int_0^{\infty} \phi(b \mid \lambda - 2\tau\lambda, c\lambda) e^{-2\tau(1-\tau)\lambda} d\lambda, \quad c, \tau > 0,$$

where $\rho_q(b) = |b|/2 + (q - 1/2)b$ is the check-loss function (Polson & Scott, 2013). 115

Polson & Scott (2011) derive this as a direct consequence of the lasso identity $\int_0^{\infty} p/(2\pi\lambda)^{1/2} \exp\{-(p^2\lambda + q^2\lambda^{-1})/2\} d\lambda = e^{-|pq|}$. Applying the Liouville identity yields

$$\int_0^{\infty} f\left(ax + \frac{b}{x}\right) x^{-1/2} dx = a^{-1/2} \int_0^{\infty} f\left\{2(ab)^{1/2} + y\right\} y^{-1/2} dy, \quad a, b > 0.$$

Setting $f(x) = e^{-x}$, $a = p^2/2$, and $b = q^2/2$ we get

$$\begin{aligned} \int_0^{\infty} \frac{e^{-(p^2\lambda + q^2\lambda^{-1})/2}}{\lambda^{1/2}} d\lambda &= \frac{2^{1/2}}{p} \int_0^{\infty} e^{-|pq| + y} y^{-1/2} dy \\ &= \frac{2^{1/2} e^{-|pq|}}{p} \int_0^{\infty} e^{-y} y^{-1/2} dy = \frac{(2\pi)^{1/2} e^{-|pq|}}{p}. \end{aligned} \quad 120$$

Hans (2011) shows that the elastic-net regression can be recast as a global-local mixture with a mixing density belonging to the orthant-normal family of distributions. The orthant-normal prior on a single regression coefficient, β , given hyper-parameters λ_1 and λ_2 , has a density function with the following form:

$$p(\beta \mid \lambda_1, \lambda_2) = \begin{cases} \phi(\beta \mid \frac{\lambda_1}{2\lambda_2}, \frac{\sigma^2}{\lambda_2}) / 2\Phi\left(-\frac{\lambda_1}{2\sigma\lambda_2^{1/2}}\right), & \beta < 0, \\ \phi(\beta \mid \frac{-\lambda_1}{2\lambda_2}, \frac{\sigma^2}{\lambda_2}) / 2\Phi\left(-\frac{\lambda_1}{2\sigma\lambda_2^{1/2}}\right), & \beta \geq 0. \end{cases} \quad (11)$$

3. CONVOLUTION MIXTURES

Another interesting area of application is convolution mixtures and marginal densities for location-scale mixture problems. We show that the Cauchy convolution (Pillai & Meng, 2016)

and inverse-gamma convolution can be derived similarly (Polson & Scott, 2012). Bhadra et al. (2016b) shows that the regularly varying tails of half-Cauchy priors work well for low-dimensional functions of normal vector mean, where flat priors give poorly calibrated inference.

LEMMA 1. Let $X_i \sim \mathcal{C}(0, 1)$ ($i = 1, 2$) be Cauchy distributed random variates, then $Z = w_1 X_1 + w_2 X_2 \sim \mathcal{C}(0, w_1 + w_2)$, where $w_1, w_2 > 0$.

LEMMA 2. Let $X_i \sim \mathcal{IG}(\alpha t_i, \alpha t_i^2)$ ($i = 1, 2$), then $Z = X_1 + X_2 \sim \mathcal{IG}\{\alpha(t_1 + t_2), \alpha(t_1^2 + t_2^2)\}$, where $\alpha, t_1, t_2 \geq 0$, and $\mathcal{IG}(\alpha t, \alpha t^2)$ is an inverse-Gaussian random variable with density

$$f(x) = \frac{t\alpha^{1/2}e^t}{(2\pi)^{1/2}x^{3/2}} \exp\left(-\frac{\alpha t^2}{2x} - \frac{x}{2\alpha}\right), \quad x \geq 0.$$

Both of these results follow from straightforward applications of the Cauchy-Schlömilch transformation. We give a proof for the Cauchy convolution identity below.

Proof. Exploiting symmetry and the Lagrange identity $(a^2 + b^2)(c^2 + d^2) = (ac + bd)^2 + (ad - bc)^2$, leads to the convolution density

$$\begin{aligned} f_Z(z) &= 2 \int_0^\infty \frac{1}{\pi w_1(1 + x^2/w_1^2)} \frac{1}{\pi w_2\{1 + (z - x)^2/w_2^2\}} dx \\ &= \frac{2}{\pi^2 w_1 w_2} \int_0^\infty \frac{1}{\{1 + w_1^{-1} w_2^{-1} x(z - x)\}^2 + \{w_2^{-1} z - (w_1^{-1} + w_2^{-1})x\}^2} dx. \end{aligned}$$

Transforming x to $x + w_2^{-1} z(w_1^{-1} + w_2^{-1})^{-1}$ and letting $a = 1 + z^2(w_1 + w_2)^{-2}$, $b = (w_1 w_2)^{-1}$, $c = z(w_2 - w_1)\{(w_1 + w_2)w_1 w_2\}^{-1}$, $d = z(w_2 - w_1)\{(w_1 + w_2)w_1 w_2\}^{-1}$ gives

$$\begin{aligned} f_Z(z) &= \frac{2}{\pi^2 w_1 w_2} \int_0^\infty \left[\left\{ 1 + \frac{z^2}{(w_1 + w_2)^2} - \frac{x^2}{w_1 w_2} + xz \frac{w_2 - w_1}{(w_1 + w_2)w_1 w_2} \right\}^2 + x^2 \left(\frac{w_1 + w_2}{w_1 w_2} \right)^2 \right]^{-1} dx \\ &= \frac{2}{\pi^2 w_1 w_2} \int_0^\infty \frac{dx}{(a - bx^2 + cx)^2 + x^2 d^2} = \frac{2}{\pi^2 w_1 w_2} \int_0^\infty \frac{dx/x^2}{(a/x - bx + c)^2 + d^2}. \end{aligned}$$

If we let $y = x^{-1}$ and apply the Cauchy-Schlömilch transformation, we arrive at

$$f_Z(z) = \frac{2}{\pi w_1 w_2} \int_0^\infty \frac{dy}{2a(y^2 + d^2)} = \frac{1}{\pi w_1 w_2} \frac{1}{ad} = \frac{1}{\pi(w_1 + w_2)} \frac{1}{1 + z^2/(w_1 + w_2)^2}.$$

A simple induction argument proves that the sum of any number of independent Cauchy random variates is also another Cauchy. \square

One can also use the characteristic function of $X \sim \mathcal{C}(\mu, \sigma)$, $\psi_X(t) = \exp(it\mu - |t|\sigma^2)$, and the relation $\psi_{X+Y}(t) = \psi_X(t)\psi_Y(t)$ to derive the result in just one step. For $X = \sum_{i=1}^p \omega_i C_i$ and $C_i \sim \mathcal{C}(0, 1)$, when $\sum_{i=1}^p \omega_i = 1$ we have $\phi_X(t) = \exp(-\sum_{i=1}^p \omega_i |t|) = \exp(-|t|) = \phi_C(t)$, where $C \sim \mathcal{C}(0, 1)$.

The most general result in this category is due to Pillai & Meng (2016), who they showed the following: Let (X_1, \dots, X_m) and (Y_1, \dots, Y_m) be independent and identically distributed $\mathcal{N}(0, \Sigma)$ for an arbitrary positive definite matrix Σ , then $Z = \sum_{j=1}^m w_j X_j / Y_j \sim \mathcal{C}(0, 1)$, as long as (w_1, \dots, w_m) is independent of (X, Y) , $w_j \geq 0$ ($j = 1, \dots, m$) and $\sum_{j=1}^m w_j = 1$.

4. DISCUSSION

The Cauchy-Schlömilch and Liouville transformations not only guarantee an simple normalizing constant for $f(\cdot)$, it also establishes the wide class of unimodal densities as global-local scale mixtures. Global-local scale mixtures that are conditionally Gaussian hold a special place in statistical modeling and can be rapidly fit using an expectation-maximization algorithm, as pointed out by Polson & Scott (2013). Palmer et al. (2011) provides a similar tool for modeling multivariate dependence by writing general non-Gaussian multivariate densities as multivariate Gaussian scale mixtures.

We end our paper with conjectures that two other remarkable identities arise as corollaries of such transformation identities. The first one is a recent result by Zhang et al. (2014) that proves a uniform correlation mixture of a bivariate Gaussian density with unit variance is a function of the maximum norm:

$$\int_{-1}^1 \frac{1}{4\pi(1-\rho^2)^{1/2}} \exp\left\{-\frac{x_1^2 + x_2^2 - 2\rho x_1 x_2}{2(1-\rho^2)}\right\} d\rho = \frac{1}{2} \{1 - \Phi(\|x\|_\infty)\} , \quad (12)$$

where $\Phi(\cdot)$ is the standard normal distribution function and $\|x\|_\infty = \max\{x_1, x_2\}$. The bivariate density on the right side of (12) was introduced by Bryson & Johnson (1982) as uniform mixtures of a chi random variate with 3 degrees of freedom, but the representation as a uniform correlation mixture is a new find. We make a few remarks connected to the Erdelyi's integral identity, which is key to the proof of the uniform correlation mixture of (12).

LEMMA 3. *Erdelyi's identity, defined by*

$$\int_{1/2}^\infty \frac{e^{-x^2 z}}{4\pi z(2z-1)^{1/2}} dz = \frac{1}{2} \{1 - \Phi(x)\} , \quad x \geq 0, \quad (13)$$

follows from the Laplace transformation $(1+u)^{-1} = \int_0^\infty \exp\{-v(1+u)\} dv$.

Proof. Apply the transform $u = 2z - 1$ to the left hand side of (13), denoted by I , to obtain

$$I = \int_0^\infty \frac{e^{-x^2/\{2(1+u)\}}}{4\pi u^{1/2}(1+u)} du .$$

Using the Laplace transformation $(1+u)^{-1} = \int_0^\infty e^{-v(1+u)} dv$ yields

$$\begin{aligned} I &= \int_0^\infty \frac{e^{-x^2/\{2(1+u)\}}}{4\pi u^{1/2}} \int_0^\infty e^{-v(1+u)} dv du = \int_{v=0}^\infty \int_{u=0}^\infty \frac{e^{-(x^2/2+v)(1+u)}}{4\pi u^{1/2}} dv du \\ &= \int_{v=0}^\infty \frac{1}{4\pi} e^{-(x^2/2+v)} \int_{u=0}^\infty u^{-1/2} e^{-(x^2/2+v)u} du dv = \int_{v=0}^\infty \frac{e^{-(x^2+2v)/2}}{2(2\pi)^{1/2}} \frac{1}{(x^2+2v)^{1/2}} dv , \end{aligned}$$

and letting $z^2 = x^2 + 2v$ we get

$$I = \frac{1}{2} \int_{z=|x|}^\infty \frac{1}{(2\pi)^{1/2}} e^{-z^2/2} dz = \frac{1}{2} \{1 - \Phi(|x|)\} .$$

The second candidate is the symmetric stable distribution, defined by its characteristic function $\phi(t) = \exp(-|t|^\alpha)$, $0 < \alpha \leq 2$. It admits a normal scale mixture representation with mixing density as $f(v) = 2^{-1} s_{\alpha/2}(v/2)$, $v > 0$, where $s_{\alpha/2}$ is the positive stable density with index $\alpha/2$ (Gneiting, 1997). The exponential power density arising as a dual of the symmetric stable density also has a normal scale mixture representation with important application in Bayesian bridge

regression (Polson et al., 2014).

$$e^{-|x|^\alpha} = \int_0^\infty e^{-x\eta} g(\eta) d\eta, \quad g(\eta) = \sum_{j=1}^{\infty} (-1)^j \frac{\eta^{-j\alpha-1}}{j! \Gamma(-\alpha j)},$$

Polson et al. (2014) derive this as a limiting result of the scale-mixture of beta representation for k -montone densities and utilizing the complete monotonicity of exponential power density. Regularization, in this case, is an outcome of a normal scale mixture with respect to an α -stable random variable. We conjecture that these two results follow from the Cauchy-Schlömilch formula (1). Other potential applications include using Liouville formula to recognize and generate global-local mixtures, and to calculate higher-order closed-form moments $E(X^n)$ for random variables X that admit a global-local representation.
